Guyana Multiple Indicator Cluster Survey 5

Overview	
Identification	DDI-CCC-CSO-MICS5-v1.0
Version	Version 1.0: data used for preparation of final report tabulations
<p>Abstract</p> <p>MICS surveys are household sample surveys designed to provide up-to-date information on the situation of children and women, and to measure key indicators that allow countries to monitor progress towards the Millennium Development Goals (MDGs) and other internationally agreed upon commitments.</p> <p>Background</p> <p>The UNICEF office in Georgetown, Guyana has signed an agreement with the Ministry of Health (MoH) of Guyana to conduct a Multi-Indicator Cluster Survey (MICS) in 2013/2014.</p> <p>The Bureau of Statistics (BOS) will be in charge of planning and organizing the implementation of the survey, including the sample design. For this purpose, a survey coordinator will be hired to oversee all aspects of the survey.</p> <p>Survey Objectives</p> <p>The 2013-2014 Guyana Multiple Indicator Cluster Survey has as its primary objectives:</p> <p>To furnish data needed for monitoring progress toward goals established in the Millennium Declaration and other internationally agreed upon goals, as a basis for future action.</p> <p>To contribute to the improvement of data and monitoring systems in Guyana and to strengthen technical expertise in the design, implementation, and analysis of such systems.</p> <p>Content</p> <p>Four sets of questionnaires are used in a MICS survey: 1) a household questionnaire which is used to collect information on all de jure household members (usual residents), the household, and the dwelling; 2) a women's questionnaire administered in each household to all women aged 15-49 years; 3) a men's questionnaire administered in each household to all men aged 15-49 years; and 4) an under-5 questionnaire, administered to mothers or caretakers for all children under 5 living in the household.</p> <p>Survey plans</p> <p>The surveys are typically carried out by the Bureau of Statistics, with the support and assistance of UNICEF and other partners. Technical assistance and training for the surveys is provided through a series of regional workshops, covering questionnaire content, sampling and survey implementation; data processing; data quality and data analysis; report writing and dissemination.</p> <p>Survey results</p> <p>Results from the surveys, including national reports, standard sets of tabulations and micro level datasets will all be made widely available after completion of the surveys. Survey results are expected to become available in 2013-2015. MICS Results will also be available through the Bureau of Statistics and UNICEF's web site dedicated to monitoring the situation of children and women at www.statisticsguyana.gov.gy and www.childinfo.org. Results of the prior round of MICS can already be found at these sites.</p>	
Unit of Analysis	De jure household members (defined as members of the household who usually live in the household, which may include persons who did not sleep in the household the previous night; it does not include visitors who slept in the household the previous night but who do not usually live in the household).

	Women aged 15-49 years
	Men aged 15-49 years
	Children aged 0-4 years

Scope & Coverage	
Keywords	Enumeration Area (EA), Cluster, Base Map, Dwelling Unit, Structure, Household, Head of Household
Topics	Household members, Education, Child labour, Child discipline, Household characteristics, Insecticide treated (mosquito) nets, Indoor residual spraying, Water and sanitation, Hand washing, Salt iodization, Women's background, Access to mass media and use of information/communication technology, Fertility, Fertility/Birth History, Birth History, Desire for last birth, Maternal and newborn health, Post Natal Health Checks, Illness symptoms, Contraception, Unmet need, Female genital mutilation/cutting, Attitudes towards domestic violence, Marriage/union, Sexual behaviour, HIV/AIDS knowledge, Maternal Mortality, Tobacco and Alcohol Use, Life Satisfaction, Children's age, Birth registration, Early childhood development, Breastfeeding and Dietary Intake, Immunization, Care of illness, Anthropometry
Countries	Guyana
Geographic Coverage The survey is nationally representative and covers the whole of Guyana, this includes all administrative regions i.e. Region 1 - Region 10.	
Universe The survey covered all de jure household members (usual residents), all women aged 15-49 years resident in the household, a sub sample of men aged 15-49 years and all children aged 0-4 years (under age 5) resident in the household.

Sampling

Sampling Procedure

This report describes the results and recommendations for the sample design of the MICS 5 in Guyana based on a review and preparation of a sampling frame produced with minimal information from the results of the 2012 Census of Population and Housing. The only information available from the 2012 Census was a list of Enumeration Districts (these are the Enumeration Areas in Guyana) with the following information for every census ED:

1. Region
2. Coastal or interior
3. Urban/Rural
4. Number of Households
5. Population

However, many EDs were very small and they had to be collapsed with adjacent EDs in order to obtain EDS of a minimum size. However, many PSUs were created containing many EDs, mostly in the sparsely populated Interior Area, which might present a problem if chosen to be in sample.

According to the 2012 census, Guyana lost 3 percent of its population when compared with the 2002 census population figures. The population loss is mostly due to high emigration and low fertility rate (TFR of 2.27). However, there were 6 percent more EDs in 2012 than in 2002 as a result of splitting large EDs into smaller ones. Many EDs in the Interior Region have very little population in vast areas. This complicates the process of collapsing EDs because in order to obtain EDs of a minimum size many small EDs have to be collapsed thus creating large areas which ultimately need to be listed if they fall in sample.

The 2013/2014 MICS 5 in Guyana will have two domains of estimation: Coastal and Interior. The sample will be chosen to also produce estimates by urban/rural domains. To determine the sample size by Coastal and Interior areas, the indicator "Underweight Prevalence" was used in the MICS spreadsheet. It produced a sample size of 8,623. Manifold stated that the sample size was established at 6,000 households due to budgetary and logistical constraints.

Manifold also stated that the BOS wanted to take 20 households per PSU thus determining the number of PSUs to be used in the survey as 300.

The allocation to the different domains is usually done proportionally to the size of the domain. However, the Interior domain represents 12.52 percent of the population. This means that only 30 PSUs would have been allocated to the Interior domain, which is very low. Therefore, it was decided to increase the number of PSUs in the Interior domain to 80 in order to obtain higher reliability in the estimates.

The remaining 220 PSUs were allocated to the Coastal domain where 87.68 percent of the population resides. The allocation of the remaining 220 PSUs were done proportionally to the size of the urban and rural areas of the Coastal domain. This scheme allocated 70 PSUs to the urban area of the Coastal domain and 150 to the rural area of the Coastal domain.

Since the sample design specialist did not have any information of the average number of women aged 15 to 49 or men aged 15 to 49, it was not possible to calculate the duration of the fieldwork. The same applies to the estimated number of women and men in sample. However, it is expected that the number of children in sample will be at least 3,600.

Stratification

In order to increase the efficiency of the sample design of the MICS 5 in Guyana the sampling frame must be stratified into homogenous strata. The first level of stratification generally corresponds to the domains of estimation, that is, the Coastal and Interior areas. The Coastal domain of estimation will be divided into urban and rural strata. The Interior domain is fully rural. The survey results will be published by Coastal and Interior domains and by national urban/rural. Within each geographic stratum the PSUs should be ordered geographically to obtain an implicit stratification when systematic selection

is used. This implies that the codes that define the newly created EDs must reflect a serpentine disposition so that the systematic selection of EDs will be widely distributed in the stratum.

Selection of Households within the Sample PSUs

In countries with a low average number of persons per household and low fertility, as is the case of Guyana, a household listing of the sample PSUs to determine the number of households that have under 5 children will take place in the field prior to interviewing. This is done to increase the number of households with children in the sample. If random selection is carried out without this type of listing, it might happen that the number of households with children in sample might be small. There might even be cases in which no household may have children under 5 inside the PSU.

Therefore a household listing to identify households with children under 5 will be done in the field prior to interviewing. This is done to ensure that a certain number of households in the sample will have children and a certain number will not. Therefore, within each PSU the households in the listing must be stratified in two groups: (1) households with children under 5 and (2) households without children in that age group.

From the household listing sheets 12 households with children under 5 will be selected and 8 without children in that age group. If a PSU were to have, say, 5 households with children under 5, these will be all selected and the other 15 will not have any children under 5 in that PSU. This will allow the reliability of the estimates to be kept at an acceptable level thus preventing that all the households selected have children under 5 because, if this were the case, the sample size would be high and this will exacerbate the complexity of the field work.

To summarize:

a. Households With Children Under 5

1. Select 12 households with children under 5 out of the 20 in the PSU.
2. All eligible children under 5 will be interviewed.
3. All eligible women between 15 and 49 will be interviewed.
4. The interview for men aged 15 to 49 should be conducted in every other household. This means that half the households with children under 5 should have interviews for men, that is, 6 households. The households that will be administered the man's questionnaires should be selected at random.

b. Households Without Children Under 5

1. All eligible women aged 15 to 49 should be interviewed.
2. The interview for men aged 15 to 49 should be conducted in every other household. This means that half the households without children under 5 should have interviews for men, that is, 4 households. The households that will be administered the man's questionnaires should be selected at random.
3. For the 8 remaining households without children under 5, all eligible women between 15 and 49 should be interviewed and 4 out of the 8 households in this substratum should have man interviews.

To select households from the household listing sheets, proceed as follows:

1. Within each listed PSU identify the valid households, that is, the households that are occupied permanently and have children under 5 and its complement.
2. This operation will create two substrata: one with children under 5 and one without.
3. Within each substratum inside the sample PSU, identify the valid number of households. Let M'_{hi} , where the subindex h refers to the substratum and the subindex i refers to the PSU. This operation can be performed separately using an EXCEL

spreadsheet. The substratum $h = 1$ represents the households with children under 5 and the substratum $h = 2$ the other households.

4. The j -th sample households within substratum h is obtained as follows:

$$[A_{hi} + (j-1) * I_{hi}] + 1$$

for $j = 1, \dots, m_{hi}$

omitting the decimals in the results, without rounding.

where,

$I_{hi} = M'_{hi}/m_{hi}$ = selection interval within the I -th PSU of substratum h .

M'_{hi} = Number of valid households within the I -th PSU in substratum h .

$m_{hi} = 12$ in substratum $h = 1$ and 8 in substratum $h = 2$.

A_{hi} = Random number between 0 and I_{hi} , including 0 and excluding I_{hi}

Note: when the decimals are omitted the number 0 must be included and I_{hi} excluded to preserve the probabilities of selection uniform. In EXCEL the function +RAND() provides a random number between 0 and 1, call it "a". To obtain a random number between 0 and I_{hi} , multiply the number "a" by the selection interval to obtain a random number between 0 and I_{hi} .

5. Within the PSU I and the substratum h , the probabilities of selection are uniform and equal to the reciprocal of the selection interval. That is,

a. For substratum $h = 1$

where M'_{1i} = number of listed households in PSU I that have children under 5.

b. For substratum $h = 2$

where M'_{2i} = number of listed households in PSU I that do not have children under 5.

F. Splitting of Large PSUs

Since the sampling frame is about a year old it is possible that some PSUs might have undergone changes in the number of housing units or households for several reasons. It may happen that at the time of the listing some PSU might have undergone changes in the number of housing units and that the change be much bigger than the average number of households established for a PSU (between 100 and 200 housing units). If this were the case, the PSU must be split (segmented) as follows:

1. Before carrying out the listing, obtain a quick count of the number of housing units in the PSU. If the quick count produces a number that is near the average PSU size, begin with the listing operation.

2. If the quick count produces numbers that are larger than 200, it will be necessary to split the PSU as follows:

3. When creating segments, it is important to create them ensuring that they have fixed and identifiable boundaries in the field so that the interviewer can find the sample segment at the time of interviewing.

4. Assign a sequential number from 1 to k, where k represents the number of segments that were created from the PSU. A random number table can be used to select the sample segment.
5. Once the segment is chosen, the household listing operation can take place

Sample Size and Sample Allocation

The target sample size for the Guyana MICS was established at 6000 households. For the calculation of a minimum sample size, the key indicator considered was the underweight prevalence. The following formula was used to estimate the minimum required sample size for this indicator at the Coastal and Interior levels:

where:

n = the required sample size, expressed as number of households

4 = is a factor to achieve the 95 per cent level of confidence

r = is the predicted or anticipated prevalence (coverage rate) of the indicator

1.1 = is the factor necessary to raise the sample size by 10 per cent for nonresponse

f = is the shortened symbol for deff (design effect)

$0.12r$ = is the margin of error to be tolerated at the 95 per cent level of confidence, defined as 12 per cent of r (relative sampling error of r)

p = is the proportion of the total population upon which the indicator, r , is based

NH = is the average household size.

For the calculation, r (underweight prevalence) was assumed to be 12.4 percent. The value of deff (design effect) was taken as 1.661 based on estimates from previous surveys, p (percentage of children under 5 in the total population) was taken as 8.4 percent, and NH (average household size) was taken as 4.1 households.

The resulting number of households estimated from this exercise was 8,623 households which is the minimum sample size needed to achieve the desired reliability. Nonetheless, it was decided that this round of MICS should be as comparable, as possible, in size to the previous round of MICS conducted in Guyana in 2006. In that round, the sample size utilized was 5,280, but only 5,008 households were successfully interviewed. Therefore, the sample size was established at 6,000 households.

Guyana consists of ten (10) administrative regions. The first stage sample frame was prepared by delineating these Regions into rural and urban areas (strata). Four of the administrative Regions are considered exclusively rural, while the other four comprise both urban and rural strata. In effect, there are 14 strata; 10 rural (one for each administrative Region) and 4 urban. Regions 2, 4, 6 and 10 have both, urban and rural. For this survey, only 2 domains (Interior and Coastal) were necessary to achieve the objectives. The Interior frame includes 5 of the rural strata while the coastal frame is made up of the remaining 5 rural strata plus the 4 urban strata. The coastal frame is implicitly stratified thereby ensuring that the urban and rural populations are proportionately represented in the sample.

The Interior domain only accounts for 12.32 percent of Guyana's population (Census 2012). Proportionate allocation would result in only 740 households being assigned to the interior sample. This would have been too small to be useful as a minimum of 1,600 households was needed to provide results with the prescribed reliability. The sample size in the coastal domain was hence 4,400 households.

Balancing costs, reliability and time, twenty (20) households, different from the 2006 MICS in which 24 households were chosen per cluster, were selected per cluster resulting in 300 clusters being chosen for the entire country; 80 for the interior sample and 220 for the coastal sample.

Sampling Frame and Selection of Clusters

The 2012 census frame was used for the selection of clusters. Census enumeration districts (EDs) were defined as primary sampling units (PSUs), and were selected from each of the sampling domains by using systematic p.p.s. (probability proportional to size) sampling procedures, based on the estimated sizes of the EDs from the 2012 Population Census. The first stage of sampling was thus completed by selecting the required number of EDs from each of the 2 domains (Coastal and interior areas separately).

Listing Activities

Even though the sample frame (the 2012 Population Census) is more or less up-to-date, the maps and household listings of the selected clusters were updated prior to selecting the households. Both coastal and interior area sample EDs were canvassed and listed in order to obtain a second-stage sampling frame for the selection of 12 households with children under 5 and 8 without.

The mapping and the listing of the households of the selected clusters were done by the 10 survey teams formed for the execution of the field work on the coast (Section 1 on Training and Fieldwork). Each team was assigned 12 to 16 clusters depending on the geographic layout to the areas. The respective supervisors were given the census maps of the clusters assigned to them, complete with indications of the buildings within the clearly defined boundaries.

The supervisors were also given blank copies of Cluster listing Schedules to be used to list the households found in the cluster. Prior to selecting the households for each cluster selected, the team assigned to the cluster, headed by a supervisor, mapped and listed all the buildings and households found in the cluster.

The supervisors and editors identified the boundaries of the clusters, and then decided on the most suitable location to start listing. Each building found in the Cluster was given a number in sequence on the map starting from 001, 002, 003, etc. These numbers corresponded with those on the Cluster listing schedules. The listings were done in a systematic manner as far as feasible so as to avoid missing households.

Selection of Households

At the end of the mapping and listing exercise for each cluster, the total population, number of households, and buildings were then related to the BOS/ coordinator. These figures were then compared with those of the census in an effort to validate the findings. The 20 households were selected only after the BOS/ coordinator was satisfied that the entire cluster was listed. The selected was carried out using systematic selection procedures.

Weighting

1. Weighting

For the estimates to be representative of the population, we have to multiply the data by a weighting factor. The basic weighting factor for each household is equal to the inverse of the probability of selection which is calculated multiplying the probabilities in each stage. If the sample is chosen in two stages (as will be the case in Guyana) there will be two probabilities, one for the first-stage selection (PSUs) and one for the second-stage selection (the households). This basic weighting factor must be added to the data base. In addition, we have to calculate the weighting factors for women, for children and for men interviewed in each household.

The probabilities of selection in each stage must be kept in an EXCEL sheet including information about the frame for each sample PSU and for each household to be able to calculate the final probabilities and the corresponding weighting factors. In the same EXCEL sheet, after having carried out the household listing, register the total number of households listed with children under 5 and without children under 5, as well as the final number of interviewed households for these two groups each PSU. Two weighting factors will be calculated for each sample PSU: one for the households with children under 5 and another for the other households without children under 5.

With a two-stage sample design with stratification, the probability of selection of the households with children under 5 within each sample PSU is given by the following expression:

where:

$\phi(w.c.)$ = probability of selection of households with children under in the I-th PSU of stratum h (Region by domain by urban/rural)

NH = number of sample PSUs selected in stratum h

M_{hi} = total number of households in the frame within the I-th PSU of stratum h

mH = total number of households in the frame for stratum h

$m_{hi}(w.c.)$ = number of sample households with children under 5 in the I-th PSU of stratum h

$M'_{hi}(cN)$ = total number of households with children under 5 listed in the I-th PSU of stratum h

The probability of selection of households without children under 5 is calculated as follows:

where:

$\phi(w.o.c.)$ = probability of selection of the sample households without children under 5 in the I-th sample PSU of stratum h

$m_{hi}(w.o.c.)$ = number of sample households without children under 5 selected in the I-th sample PSU of stratum h

$M'_{hi}(w.o.c.)$ = total number of households without children under 5 listed in the I-th sample PSU of stratum h

The basic weighting factors are equal to the inverse of the probability of selection and are obtained as follows:

where:

$m_{hi}(w.c.)$ = basic weighting factor for households with children under 5 in the I-th sample PSU of stratum h

and

where:

$m_{hi}(w.o.c.)$ = basic weighting factor for households without children under 5 in the I-th sample PSU of stratum h

Based on the proposed sampling of choosing 12 households with children and 8 without children, the weight factors of the households without children will be larger than the factors for the households with children. The variability of the factors within each stratum will depend on the proportion of households with children under 5 in each sample PSU.

When the listed households are stratified in two groups (with children under 5 and without) it is possible that some selected households in the stratum with children under 5 do not have any children under 5 at the time of interviewing. Also the reverse may happen: households without children at the time of the listing have children under 5 at the time of the interview. For those cases, the probabilities and the weighting factors will depend on the stratum in which the household was selected.

Therefore, it is important to include a code for the original stratum (with and without children) in which each household was selected in order to correctly calculate the weighting factors.

The basic weighting factors may have to be adjusted due to non-response in a given sample PSU (or within a stratum if the non-response rate is higher than 50%). Since the factors were calculated separately for the households with and without children at the PSU level, it would be convenient to adjust the factor at this level. The final adjusted weighting factor for households with children under 5 is expressed as follows:

where:

$m'_{hi}(wc)$ = total number of valid households (occupied) with children under 5 selected in the I-th sample PSU of stratum h

$m''_{hi}(w.c.)$ = number of sample households with children under 5 that have completed questionnaires in the I-th sample PSU of stratum h

For the households without children, the factors will be adjusted in a similar manner.

Once the household weighting factors have been adjusted they have to be normalized in order to use relative factors in the data analysis. This way, the sum of the relative factors will equal the number of sample households at the national level. To normalize the weighting factors, divide each factor by the average factor at the national level, that is, the sum of the factors for all the households in sample divided by the number of households in sample.

Considering that sometimes it is not possible to complete a woman questionnaire for each eligible woman in the sample households, it is necessary to calculate a woman factor where there is non-response at the woman level which is applied to the household factor at the PSU level, separately for households with children and for households without children. The final woman factor is given by:

where:

$wf_{hi}(w.c.)$ = adjusted factor for women data in households with children under 5 in the I-th sample PSU of stratum h

$f_{hi}(w.c.)$ = total number of women 15 to 49 identified in the questionnaire for households with children under 5 in the I-th sample PSU of stratum h

$f'_{hi}(w.c.)$ = number of women with completed interviews for households with children under 5 in the I-th sample PSU of stratum h

A similar adjustment will have to be made for the households without children under in each sample PSU if necessary.

The same situation arises when a questionnaire for a child under 5 is not completed in some sample household. It will be necessary to calculate a child factor due to non-response that must be applied to the weighting factor of the household with children. This factor for children under 5 due to non-response is obtained as follows:

where:

$wn_{hi}(w.c.)$ = adjusted weighting factor for data in the children questionnaires in the I-th sample PSU of stratum h

n_{hi} = total number of children under 5 identified in the questionnaire for all sample households in the I-th sample PSU of stratum h

n_{hi} = number of children with completed interviews for all sample households in the i -th sample PSU of stratum h

Both the woman factor and the child factor must be normalized the same way as the household factors were normalized. Each woman weighting factor must be divided by the national average of the woman factors and each child factor must be divided by the national average of all the child factors. The same procedure must be used to adjust the man factors.

Calculation of Sample Weights

The Guyana Multiple Indicator Cluster Survey sample is not self-weighted. Essentially, by allocating equal numbers of households to each of the domains (coastal/interior), different sampling fractions were used in each domain since the size of the domain varied. For this reason, sample weights were calculated and these were used in the subsequent analyses of the survey data.

The major component of the weight is the reciprocal of the sampling fraction employed in selecting the number of sample households in that particular sampling domain:

The term f_h , the sampling fraction at the h -th stratum, is the product of probabilities of selection at every stage in each sampling domain:

where P_{ih} is the probability of selection of the sampling unit in the i -th stage for the h -th sampling domain.

Since the estimated numbers of households per ED prior to the first stage selection (selection of primary sampling units) and the updated number of households per ED were different, individual sampling fractions for households in each cluster were calculated. The sampling fractions for households in each cluster therefore included the probability of selection of the ED in that particular sampling domain and the probability of selection of a household in the sample cluster.

A second component which has to be taken into account in the calculation of sample weights is the level of non-response for the household and individual interviews. The adjustment for household non-response is equal to the inverse value of:

$$RR = \text{Number of interviewed households} / \text{Number of occupied households listed}$$

After the completion of fieldwork, response rates were calculated for each sampling domain. These were used to adjust the sample weights calculated for each cluster. Response rates in the Guyana Multiple Indicator Cluster Survey are shown in Table HH.1 in this report.

Similarly, the adjustment for non-response at the individual level (women, men and under-5 children) is equal to the inverse value of:

$$RR = \text{Completed women's (men or under-5's) questionnaires} / \text{Eligible women (men or under-5's)}$$

Numbers of eligible women, men and under-5 children were obtained from the household listing in the Household Questionnaire in households where interviews were completed.

The unadjusted weights for the households were calculated by multiplying the above factors for each Cluster. These weights were then standardized (or normalized), one purpose of which is to make the sum of the interviewed sample units equal the total sample size at the national level. Normalization is performed by multiplying the aforementioned unadjusted weights by the ratio of the number of completed households to the total unadjusted weighted number of households. A similar standardization procedure was followed in obtaining standardized weights for the women's, men's and under-5's questionnaires.

Sample weights were appended to all data sets and analyses were performed by weighting each household, woman, man or under-5 with these sample weights.
